Jurusan : Teknik Sipil FTSP – ITS
Dosen Pembimbing : Prof. Dr. Ir. Nadjadji Anwar, M.Sc

Abstrak

Daerah Irigasi (DI) Cau terletak di Desa Wungu, Kecamatan Wungu, Kabupaten Madiun Jawa Timur dan memiliki luas area 1200 Ha dengan sumber air irigasi dari Kali Catur melalui bendung Cau. Dengan luas tersebut maka dibutuhkan sistem irigasi yang baik. Tetapi terbatasnya jumlah air di musim kemarau dapat mengurangi pemberian air ke sawah. Untuk memaksimalkan produksi tani perlu peningkatan produktifitas lahan dan pemberian air yang teratur sesuai dengan kebutuhan dan persediaan.

Untuk analisa optimasi ini digunakan program linear Quantity Methods for Windows 5 dengan input kebutuhan air tiap jenis tanaman dan debit andalan sebagai kendala/batasan untuk pengoperasian program linier. Output dari program ini ialah luasan sawah maksimum jenis tanaman, musim tanamnya dan keuntungan hasil tani yang didapat.

Dalam Tugas Akhir ini didapatkan beberapa alternatif rencana pola tanam yang menghasilkan keuntungan terbesar yaitu pola tanam padi-padi-tebu, padi-palawija-tebu, palawija-palawija-tebu pada alternatif 2 dengan masa tanam Nopember 2 dengan keuntungan Rp 50.780.913.906 dan intensitas tanam 194 %.

Kata Kunci : optimasi , irigasi , pola tanam , metode linier

Abstract

Irrigation Area (DI) Cau is located in Wungu Village, Wungu District, Madiun District of East Java and has an area of 1200 Ha with irrigation water source from Catur River through Cau dam. With the area is required a good irrigation system. But the limited amount of water in the dry season can reduce the provision of water to the fields. To minimize the production of farmers, it is necessary to increase the productivity of land and provide regular water supply according to needs and supplies.

For this optimization analysis is used linear program Quantity Methods for Windows 5 with the input water needs of each type of plant and debit pledge as a constraint / limit for the operation of linear program. The output of this program is the width of the maximum rice field type of plant, the planting season and the benefits of farming results obtained.

In this final project, there are several alternative plan of cropping pattern that produces the greatest advantage that is rice-rice-cropping pattern, rice-palawija-sugar cane, palawija-palawija-sugar cane in alternative 2 with planting period November 2 with profit Rp 50.780.913.906 and intensity Planting 194%

Key words : optimization, irrigation, cropping pattern, linear programming

KATA PENGANTAR

Puji dan syukur diucapkan kehadiran Allah SWT yang telah melimpahkan rahmat dan hidayah-Nya sehingga Penulis dapat menyelesaikan tugas akhir yang berjudul “Studi Peningkatan Produktifitas Tanaman Daerah Irigasi Cau Kabupaten Madiun Dengan Program Linier”.

Tugas akhir ini disusun sebagai persyaratan kelulusan pada Program Studi Teknik Sipil FTSP ITS Surabaya.

Dalam penyusunan Tugas Akhir ini, Penulis banyak mendapatkan saran, dukungan, bimbingan serta bantuan dari pihak-pihak yang telah membukakan pikiran pikiran Penulis, bahwa sesungguhnya pengalaman dan pengetahuan adalah guru yang terbaik. Oleh karena itu, dengan segala hormat dan kerendahan hati, Penulis mengucapkan terima kasih kepada:

1. Ayah, Ibu yang selalu mendoakan dan memberikan dukungan.
2. Bapak Prof. Dr. Ir. Nadjadji Anwar, M.Sc dan Dosen Jurusan Teknik Sipil ITS yang telah membimbing dan memberikan pelajaran yang bermanfaat selama kuliah.
3. Dinas Pekerjaan Umum Pengairan Jawa Timur, UPT PSDAWS Madiun yang telah membantu banyak dalam pemberian data untuk pengerjaan tugas akhir ini.
4. Teman-teman yang saya sayangi yang selalu saling mendukung, memberikan semangat dan membantu dalam hal apapun termasuk dalam pengerjaan tugas akhir ini. Terima kasih banyak juga sudah mau meluangkan waktunya buat mengantar survey jauh-jauh ke Madiun (hehe)

Dalam penyusunan tugas akhir ini, Penulis menyadari masih terdapat kekurangan dan kesalahan karena keterbatasan ilmu pengetahuan dan wawasan yang dimiliki. Oleh karena itu, Penulis memohon maaf atas segala kekurangan dan kesalahan tersebut, saran dan kritik yang membangun sangat diharapkan untuk

pelajaran dan perbaikan selanjutnya. Semoga tulisan ini dapat bermanfaat bagi Penulis, institusi pendidikan, dan masyarakat.

Surabaya, Juli
2017

Penulis

“Halaman ini sengaja dikosongkan”

BAB I

PENDAHULUAN

1.1 Umum

Indonesia merupakan negara agraris, yang sebagian besar penduduknya bermata pencaharian sebagai petani. Ini dikarenakan tanah di Indonesia sangat subur dan cocok sekali bila dimanfaatkan sebagai lahan pertanian. Salah satu aspek penting dalam mengelolah lahan pertanian adalah adanya sistem pengairan yang baik. Demi tercapainya sistem pengairan yang baik perlu diadakanya penelitian lebih lanjut mengenai konsep operasional dan pembagian air, serta dilakukan proses pemeliharaan jaringan irigasi.

Sistem irigasi dapat dikatakan baik apabila mampu memenuhi kebutuhan air untuk tanaman secara maksimal, sehingga dapat mengurangi jumlah lahan yang bero (tidak dapat ditanami). Dengan hal tersebut diharapkan dapat meningkatkan hasil produksi tanam, dan tentunya dapat menambah penghasilan bagi petani, pedagang maupun masyarakat sekitar.

1.2 Latar Belakang

Sebagian besar wilayah Kabupaten Madiun merupakan daerah pertanian, oleh sebab itu sebagian besar penduduknya bermata pencaharian sebagai petani. Daerah Irigasi Cau memiliki luas total 1200 Ha. Dengan luas tersebut maka dibutuhkan sistem irigasi yang baik. Penggunaan air irigasi di Kabupaten Madiun tidak seimbang dengan ketersediaan air yang ada. Sehingga diperlukan suatu pengelolaan system irigasi yang baik. Sistem irigasi yang baik ditentukan oleh keseimbangan antara jumlah air yang tersedia di lahan dengan kebutuhan air pada tanaman.

Akan tetapi pada kenyataannya di lapangan, jumlah air yang tersedia di lahan tidak merata. Adapun

problematika jumlah air tidak merata disebabkan oleh pengoperasian pintu yang tidak teratur, banyaknya bangunan irigasi yang rusak sehingga produktifitas tanaman belum optimum, intensitas tanam rata-rata belum dapat terpenuhi serta pola tanam yang belum efektif.

Maka dari itu, perlu dilakukan “Studi Peningkatan Produktifitas Tanaman Daerah Irigasi Cau Kabupaten Madiun Dengan Program Linier”. Bertujuan untuk meningkatkan produktifitas tanaman. Melalui alternatif pola tanam dapat diperoleh hasil produksi panen yang maksimal. Dalam hal ini menggunakan program linier Quantity Methods for Windows 5 untuk membantu menyelesaikan masalah tersebut. Dengan memaksimalkan daerah pertanian yang ada secara tidak langsung perekonomian di daerah irigasi juga akan meningkat. Selain dapat mengoptimalkan hasil produksi panen, pola tanam juga dapat meningkatkan pendapatan petani dan perekonomian di Kabupaten Madiun.

1.3 Rumusan Masalah

1. Bagaimana kondisi intensitas tanam ekisting pada Daerah Irigasi Cau?
2. Berapa kebutuhan air tanaman untuk pola tanam pada Daerah Irigasi Cau setelah di optimasi?
3. Bagaimana pola tanam setelah dioptimasi berdasarkan ketersediaan air irigasi pada Daerah Irigasi Cau?
4. Berapakah besar keuntungan produksi hasil pertanian yang diperoleh petani dari hasil produksi?

1.4 Batasan Masalah

Adapun batasan masalah yang meliputi tugas akhir ini adalah :

1. Data debit yang digunakan untuk perhitungan adalah data debit intake tahun 2006-2015 (Sumber: UPT PSAWS Dinas Pengairan Madiun)

2. Data curah hujan yang diggunakan adalah curah hujan daerah Madiun dari Dinas Pekerjaan Umum Pengairan Propinsi Jawa Timur tahun 2006-2015
3. Skema Jaringan Daerah Irigasi Madiun dari Dinas Pekerjaan Umum Pengairan Propinsi Jawa Timur
4. Data klimatologi yang digunakan pada tahun 2012-2016 dari Dinas Pekerjaan Umum Pengairan Propinsi Jawa Timur
5. Pola tanam ekisting yang digunakan adalah “Penetapan Pola Tanam Daerah Irigasi Cau Kabupaten Madiun tahun 2011-2016”
6. Tidak memperhitungkan harga lahan dan biaya pelaksanaan pertanian.

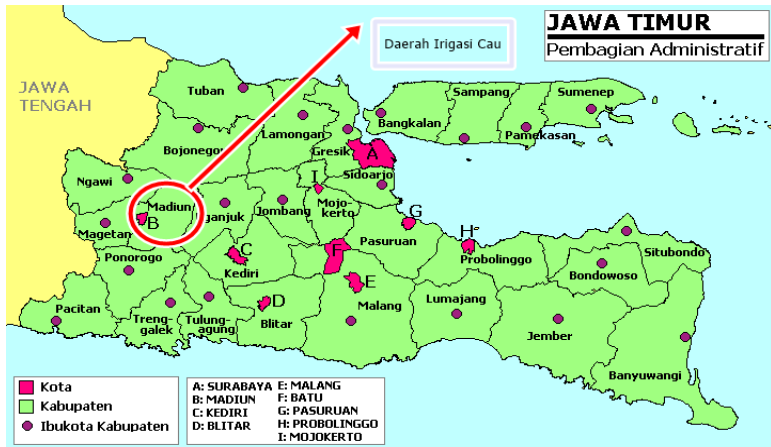

1.5 Tujuan

1. Mengetahui intensitas tanam pada Daerah Irigasi Cau.
2. Mengetahui kebutuhan air tanaman dengan debit yang tersedia di Bendung Cau.
3. Mengetahui pola tanam yang telah dioptimasi berdasarkan ketersediaan air irigasi.
4. Mengetahui keuntungan produksi hasil pertanian yang diperoleh dari hasil optimasi.

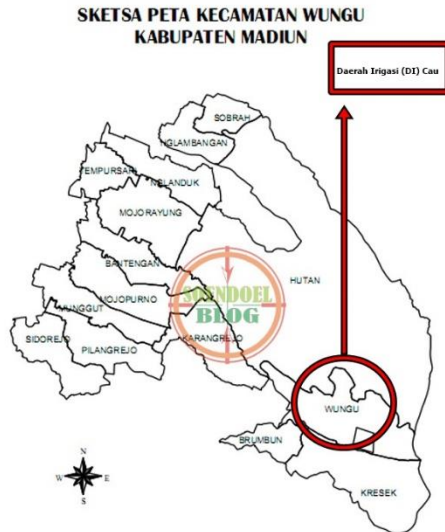

1.6 Manfaat Penelitian

Optimasi pola tanam ini dilakukan agar intensitas tanam yang baru yang dihasilkan oleh optimasi pola tanam rencana dapan menghasilkan keuntungan berupa hasil panen yang maksimal. Karena hasil panen meningkat, maka diharapkan ketersediaan bahan pangan dan kondisi ekonomi masyarakat juga meningkat.

1.7 Peta Lokasi

BAB II

TINJAUAN PUSTAKA

2.1 Data Teknis

Data teknis adalah data yang menjelaskan tentang kondisi suatu objek secara kualitas dan bersifat valid. Informasi yang ada dalam data teknis adalah hasil pengukuran atau pengamatan suatu variabel yang berbentuk angka dan frase.

2.1.1 Peta Topografi

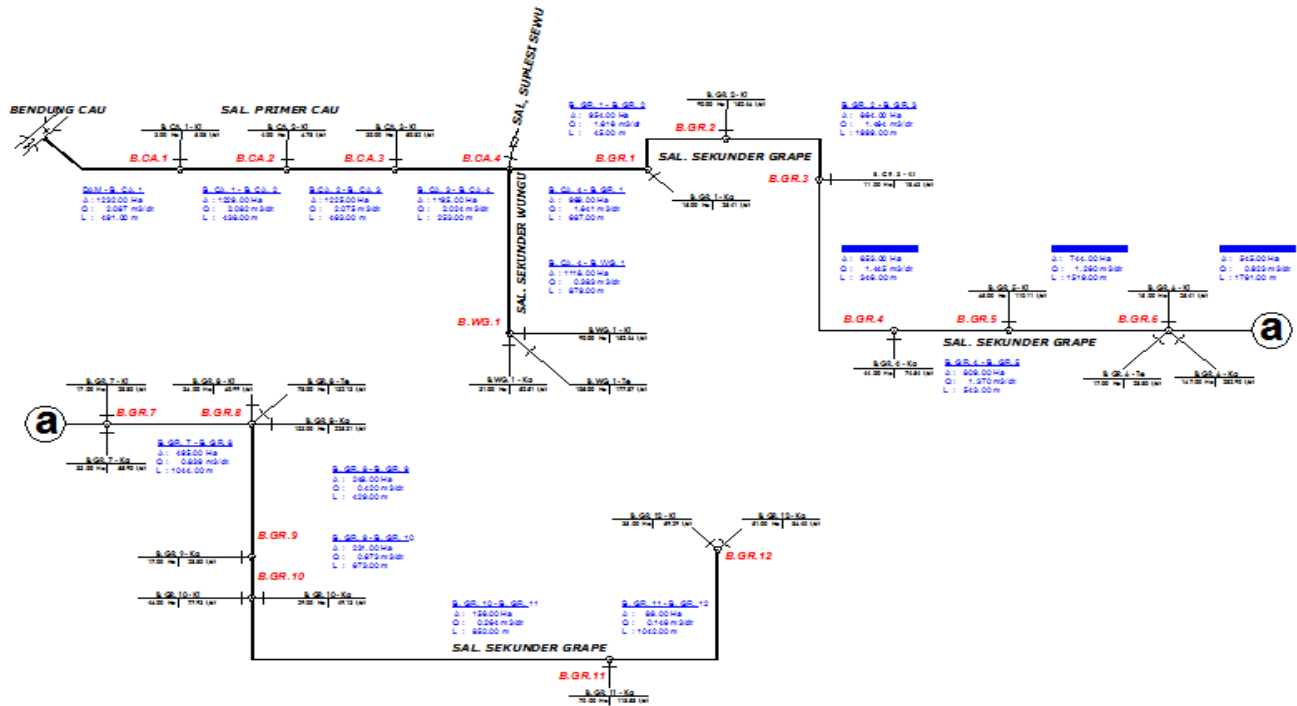

Peta topografi berfungsi memberikan informasi batas Daerah Aliran Sungai. Selain itu, letak ketinggian suatu lokasi dari permukaan air laut berpengaruh terhadap suhu dan kelembapan udara, dimana kedua hal tersebut dapat mempengaruhi pertumbuhan tanaman. Kondisi Daerah Irigasi (DI) Cau dengan luas 1.200 Ha secara administratif terletak di daerah desa Wungu, Kecamatan Wungu, Kabupaten Madiun. Kondisi alam di kecamatan Wungu ini relatif berbukit.

Adapun batas – batas wilayah Jaringan Irigasi Cau sebagai berikut :

- Sebelah Utara : Desa Mojoyayung, Kecamatan Wungu
- Sebelah Timur : Desa Kwiran, Kecamatan Kare
- Sebelah Selatan : Desa Banjarsari Kulon, Kecamatan Dagangan
- Sebelah Barat : Desa Mojopurno, Kecamatan Wungu

2.1.2 Skema Daerah Irigasi

Daerah Irigasi (DI) Cau mempunyai luas areal baku sawah seluas 1200 Ha, untuk lebih detailnya ditunjukkan pada Gambar 2.1

Gambar 2. 1 Skema Daerah Irigasi

2.2 Data Hidrologi

Data hidrologi pada studi ini nantinya akan dibuat perhitungan curah hujan rata-rata, curah hujan efektif dan debit andalan yang dipengaruhi oleh keadaan klimatologi daerah irigasi yang akan diamati.

2.2.1 Data Curah Hujan

Perhitungan curah hujan menggunakan metode Poligon Thiessen menentukan rata-rata terbobot (*weighted average*) masing-masing stasiun hujan terhadap luas daerah pengaruhnya berdasarkan poligon yang dibentuk (menggambarkan garis-garis sumbu pada penghubung antara dua atau lebih stasiun hujan yang berdekatan). Metode ini diperoleh dengan membuat poligon yang memotong tegak lurus pada tengah-tengah garis penghubung dua stasiun hujan. Dengan demikian tiap stasiun hujan (R_n) akan terletak pada suatu poligon tertentu (A_n). Curah hujan rata-rata diperoleh dengan cara menjumlahkan pada masing-masing penakar yang mempunyai daerah pengaruh yang dibentuk dengan menggambarkan garis-garis sumbu tegak lurus terhadap garis penghubung dua stasiun.

Cara perhitungannya adalah sebagai berikut :

$$d = \frac{A_1.d_1 + A_2.d_2 + A_3.d_3 + \dots + A_n.d_n}{A_{\text{total}}}$$

Keterangan :

A : Luas Area (km^2)

d : Tinggi curah hujan rata-rata areal

d_1, d_2, d_3, d_n : Tinggi curah hujan di stasiun hujan

A_1, A_2, A_3, A_n : Luas daerah pengaruh stasiun hujan

Data curah hujan di Daerah Irigasi Cau diambil dari stasiun hujan yaitu stasiun Cau, Stasiun Dungus, dan Stasiun Kanigoro. Data ini diambil selama 10 tahun, yaitu tahun 2006 sampai dengan tahun 2015. Contoh gambar Poligon Thiessen dapat dilihat pada gambar 2.2 :

Gambar 2. 2 Thiessen Polygon

2.2.2 Curah Hujan Efektif

Turunnya curah hujan pada suatu wilayah lahan yang mempengaruhi pertumbuhan tanaman di wilayah tersebut. (Direktorat Jendral Pengairan, 1986). Curah hujan tersebut dapat dimanfaatkan oleh tanaman untuk mengganti kehilangan air yang terjadi akibat evapotranspirasi, perkolasi, kebutuhan pengolahan tanah dan penyiapan lahan. Curah hujan efektif merupakan curah hujan yang jatuh pada suatu wilayah dan dapat digunakan tanaman untuk pertumbuhannya. Jumlah hujan yang dapat dimanfaatkan oleh tanaman tergantung jenis tanaman. Namun, tidak semua jumlah curah hujan yang turun pada daerah tersebut dapat digunakan untuk tanaman dalam pertumbuhannya, maka disini perlu diperhitungkan dan dicari curah hujan efektifnya.

Curah hujan efektif (Reff) ditentukan berdasarkan besarnya R_{80} yang merupakan curah hujan yang besarnya dapat dilampaui sebanyak 80% atau dengan kata lain dilampauinya 8 kali kejadian dari 10 kali kejadian. Artinya, bahwa curah hujan yang terjadi lebih kecil dari R_{80} mempunyai kemungkinan hanya 20%.

Untuk mengitung curah hujan efektif dinyatakan dengan rumus berikut :

$$R_{80} = \frac{n}{5} + 1 \dots \dots \dots (2.3)$$

$$= \frac{10}{5} + 1 = 3$$

Keterangan :

Reff : R_{80} : Curah hujan efektif 80%

$n/5+1$: Rangkings curah hujan efektif dihitung dari curah hujan terkecil

n : jumlah data

2.2.3 Debit Andalan

Debit andalan adalah debit yang dapat digunakan untuk keperluan tertentu sepanjang tahunnya, dalam hal ini adalah untuk keperluan irigasi. Misalnya ditetapkan debit andalan 80% berarti akan dihadapi resiko adanya kegagalan atau debit-debit yang lebih kecil dari debit andalan sebesar 20% dari total pengamatan (Soemarto, CD: 1987). Debit andalan didapatkan dari AWLR (Automatic Water Level Recorder) di pintu intake Bendung Cau.

Perhitungan debit andalan ini dimaksudkan untuk mencari besarnya debit yang sesuai untuk keperluan irigasi berdasarkan data debit intake pada masing-masing pintu pengambilan dengan periode 10 harian. Debit tersebut nantinya akan digunakan sebagai patokan ketersediaan debit yang masuk ke jaringan irigasi.

2.3 Evapotranspirasi

Evapotranspirasi adalah peristiwa gabungan dari evaporasi dan transpirasi tumbuhan. Evaporasi merupakan proses menguapnya air dari berbagai sumber yang mengandung air. Transpirasi merupakan pergerakan air di dalam tumbuhan yang hilang melalui stomata akibat diuapkan oleh tumbuhan. Evapotranspirasi adalah bagian penting dalam siklus air karena dapat menggambarkan nilai kebutuhan lingkungan, vegetasi, dan pertanian. Faktor yang menentukan nilai evapotranspirasi adalah intensitas penyinaran matahari, kecepatan angin, temperatur udara, dan tekanan udara. Perhitungan evapotranspirasi untuk menentukan kebutuhan air disawah, dalam studi ini menggunakan metode penman modifikasi yang mengikuti metode FAO, dengan persamaan sebagai berikut :

$$E_{to} = c [W \times R_n + (1-W) \times f(u) \times (e_a - e_d)] \dots (2.4)$$

Keterangan :

E_{to} : evaporasi potensial (mm/hari)

W : factor angin

R_n : pengaruh radiasi

E_a : tekanan uap air pada suhu rata-rata

E_d : tekanan uap jenuh pada titik embun

C : factor kompensasi akibat perubahan cuaca siang dan malam

$F(u)$: fungsi yang berhubungan dengan faktor angin

2.4 Analisa Kebutuhan Air Untuk Irigasi

2.4.1 Perkolasi

Perkolasi adalah proses Bergeraknya air melalui profil tanah tidak jenuh ke dalam daerah jenuh. Faktor-faktor yang mempengaruhi perkolasi adalah tekstur tanah, permeabilitas tanah, tebal lapisan tanah bagian atas, dan letak permukaan tanah. Perkolasi dapat dihitung dengan penurunan muka air pada lubang tanah dalam waktu 60 menit. Harga perkolasi dari berbagai jenis tanah dapat dilihat pada Tabel 2.1

Tabel 2.1 Harga Perkolasi Berbagai Jenis Tanah

| Jenis Tanah | Perkolasi Vertikal (mm/hari) |
|-------------|------------------------------|
| Sandy Loam | 3-8 |
| Loam | 2-3 |
| Clay | 1-2 |

Daerah Irigasi Cau yang terletak di Kabupaten Madiun memiliki nilai perkolasi sebesar 2 mm/hari. Dalam kategori diatas, termasuk ke dalam jenis *loam*.

2.4.2 Kebutuhan Air di Sawah

Kebutuhan air untuk tanaman pada suatu jaringan irigasi merupakan air yang dibutuhkan untuk tanaman dan pertumbuhanyang optimal tanpa kekurangan air yang dinyatakan dalam Net Kebutuhan Air Lapang (Net Field Requirement, NFR).

Besarnya kebutuhan air untuk tanaman disawah ditentukan oleh beberapa faktor, yakni penyiapan lahan, penggunaan konsumtif, perkolasi dan rembesan, pergantian lapisan air dan curah hujan. Efisiensi irigasi juga diperhatikan karena faktor tersebut dapat mengurangi jumlah irigasi pada tingkat penyaluran air.

Berikut adalah rumusan yang digunakan dalam mencari besaran kebutuhan air di sawah untuk beberapa jenis tanaman: (Direktorat Jendral Pengairan, 1986)

$$\text{NFR Padi} = \text{Etc} + \text{P} - \text{Re} + \text{WLR} \dots \dots \dots (2.8)$$

$$\text{NFR Palawija} = \text{Etc} - \text{Re palawija} \dots \dots \dots (2.9)$$

$$\text{NFR Tebu} = \text{Etc} - \text{Re tebu} \dots \dots \dots (2.10)$$

Keterangan :

Etc = kebutuhan air untuk konsumtif tanaman
(mm/hari)

P = Kehilangan air akibat perkolasi
(mm/hari)

Re = Curah hujan efektif (mm/hari)

WLR = Pergantian lapisan air (mm/hari)

NFR = Kebutuhan air di sawah (mm/hari)

2.4.3 Pergantian Lapisan Air (*Water Layer Requirement*)

Pergantian lapisan air adalah jumlah air yang digunakan untuk menggantikan air yang tidak berguna untuk tanaman. (Direktorat Jendral Pengairan: 1986)

- a. Setelah pemupukan, usahakan untuk menjadwalkan dan mengganti lapisan air menurut kebutuhan.
- b. Jika tidak ada penjadwalan semacam itu, lakukan penggantian sebanyak 2 kali masing-masing 50mm (3,3

mm/hari selama ½ bulan) selama sebulan pertama dan dua bulan setelah transpalasi.

2.4.4 Kebutuhan Air untuk Penyiapan Lahan

Pada standar perencanaan irigasi disebutkan bahwa kebutuhan air untuk penyiapan lahan umumnya menentukan kebutuhan maksimum air irigasi pada suatu proyek irigasi. Ada 2 faktor penting yang menentukan besarnya kebutuhan air untuk penyiapan lahan ialah:

- a) Lamanya waktu yang dibutuhkan untuk penyiapan lahan.
- b) Jumlah air yang diperlukan untuk penyiapan lahan.

Metode yang dapat digunakan untuk perhitungan kebutuhan air irigasi selama penyiapan lahan salah satunya adalah metode yang dikembangkan oleh *Van De Goor* dan *Ziljstra* (1986). Metode ini didasarkan pada laju air konstan dalam $1/dt$ selama penyiapan lahan dan menghasilkan rumus sebagai berikut:

$$IR = (M \times e^K) / e^K - 1 \dots \dots \dots (2.11)$$

Keterangan:

- IR = kebutuhan air irigasi untuk pengolahan tanah (mm/hari)
M = kebutuhan air untuk mengganti kehilangan air akibat evaporasi dan perkolasi di sawah yang telah dijenuhkan (= $E_o + P$) (mm/hari)
 E_o = Evaporasi air terbuka (mm/hari), (= $E_{To} \times 1,10$) (mm/hari)
P = Perkolasi (mm/hari) (Tergantung tekstur tanah)
 $K = (M \times T) / S$
T = Jangka waktu penyiapan lahan (hari)
S = Kebutuhan air untuk penjenuhan ditambah dengan lapisan air 50 mm, yakni $250 + 50 = 300$ mm/hari.

Penjelasan ditunjukkan pada tabel 2.2

Tabel 2.2 Kebutuhan Air untuk Penyiapan Lahan

| E _o + P mm/ hari | T = 30 hari | | T = 45 hari | |
|-----------------------------------|---------------|---------------|---------------|-------------|
| | S = 250 mm | S = 300 mm | S = 250 mm | S=300 mm |
| 5 | 11,1 | 12,7 | 8,4 | 9,5 |
| 5,5 | 11,4 | 13 | 8,8 | 9,8 |
| 6 | 11,7 | 13,3 | 9,1 | 10,1 |
| 6,5 | 12 | 13,6 | 9,4 | 10,4 |
| 7 | 12,3 | 13,9 | 9,8 | 10,8 |
| 7,5 | 12,6 | 14,2 | 10,1 | 11,1 |

2.4.5 Kebutuhan Air Untuk Konsumtif Tanaman (Etc)

Kebutuhan air untuk konsumtif tanaman (Crop Water Requirement) merupakan kedalaman air yang diperlukan untuk memenuhi evapotranspirasi tanaman yang bebas penyakit, tumbuh di areal lahan pertanian pada kondisi cukup air dari kesuburan tanah dengan potensi dan tingkat lingkungan pertumbuhan yang baik.

Kebutuhan air untuk konsumtif tanaman ini dapat duhitung dengan menggunakan rumus:

$$Etc = Kc \times Eto \dots \dots \dots (2.12)$$

Keterangan :

Etc = Evapotranspirasi tanaman (mm/hari)
Eto = Evapotraspirasi potensial (mm/hari)
Kc = Koefisien tanaman

Untuk mengetahui koefisien tanaman dapat ditunjukkan pada Tabel 2.3

Tabel 2.3 Koefisien Tanaman

| Periode | Padi | | Jagung | Periode | Tebu |
|--------------|---------------|----------------|--------|---------|------|
| Tengah Bulan | Variasi Biasa | Variasi Unggul | | Bulan | |
| 1 | 1,1 | 1,1 | 0,5 | 1 - 0 | 0,35 |
| 2 | 1,1 | 1,1 | 0,59 | 1 - 2 | 0,8 |
| 3 | 1,1 | 1,05 | 0,96 | 2 - 2,5 | 0,9 |
| 4 | 1,1 | 1,05 | 1,05 | 2,5 - 4 | 1 |
| 5 | 1,1 | 0,95 | 1,02 | 4 - 10 | 1,05 |
| 6 | 1,05 | 0 | 0,95 | 10 - 11 | 0,8 |
| 7 | 0,95 | | 0 | 11 - 12 | 0,6 |
| 8 | 0 | | | - | - |

2.4.6 Kebutuhan Air di Pintu Pengambilan

Kebutuhan air di pintu pengambilan merupakan jumlah kebutuhan air di sawah dibagi dengan efisiensi irigasinya. Kebutuhan air di pintu pengambilan dapat dihitung dengan rumus sebagai berikut:

$$DR = \frac{NFR}{8.64} \times EI \dots \dots \dots (2.13)$$

Keeterangan :

DR = Kebutuhan air di pintu pengambilan (lt/dt/ha)

NFR = Kebutuhan air di sawah (mm/hari)

EI = Efisiensi irigasi (%)

1/8,64 = Angka konversi satuan dari mm/hari ke (lt/dt/ha)

2.4.7 Efisiensi Irigasi

Merupakan perbandingan antara debit yang dimanfaatkan oleh tanaman dengan debit yang diberikan melalui pintu pengambilan. Efisiensi irigasi memperhitungkan kehilangan air

yang terjadi dalam perjalanannya menuju petak sawah. Pada tabel 2.4 efisiensi irigasi dipengaruhi oleh besarnya jumlah air yang hilang di perjalanannya dari saluran primer, sekunder hingga tersier.

Tabel 2.4 Efisiensi Irigasi

| Jaringan | Efisiensi Irigasi (%) |
|-----------------|-----------------------|
| Primer | 80 |
| Sekunder | 90 |
| Tersier | 90 |
| Total EI | 65 |

2.5 Perencanaan Pola Tanam

2.5.1 Pola Tanam

Pola tanam adalah pengaturan penggunaan lahan pertanaman dalam kurun waktu tertentu. Pola tanam merupakan bagian atau sub sistem dari sistem budidaya tanaman, maka dari sistem budidaya tanaman ini dapat dikembangkan satu atau lebih sistem pola tanam, Pola tanam ini diterapkan dengan tujuan memanfaatkan sumber daya secara optimal dan untuk menghindari resiko kegagalan.

Pola tanam dapat digunakan sebagai landasan untuk meningkatkan produktivitas lahan. Hanya saja dalam pengelolaannya diperlukan pemahaman kaidah teoritis dan ketrampilan yang baik tentang semua faktor yang menentukan produktivitas lahan tersebut. Pola tanam adalah gambaran rencana tanam berbagai jenis tanaman yang akan dibudidayakan dalam suatu lahan beririgasi dalam satu tahun. Pola tanam seperti ditunjukkan pada tabel 2.5 :

Tabel 2.5 Pola Tanam

| Tabel 2.4 Pola Tanam | |
|----------------------|----------------------------|
| Ketersediaan Air | Pola Tanam dalam Setahun |
| Cukup banyak air | Padi - padi - polowijo |
| Cukup air | Padi - padi - bero |
| | Padi - polowijo - polowijo |
| Kekurangan air | Padi - polowijo - bero |
| | Polowijo - padi - bero |

2.6 Optimasi Menggunakan Program Linier

Program linier digunakan untuk persoalan optimasi yang mempunyai bentuk ketidaksamaan dengan syarat fungsi tujuan dan fungsi kendala (Sidharta, S.K.:1997). Komponen utama dalam optimasi menggunakan program linier, berdasarkan kerangka umum permodelan optimasi, terdiri dari variabel keputusan, ruang pilihan yang dirumuskan dengan beberapa fungsi pembatas nilai variabel keputusan yang disebut fungsi kendala, dan fungsi tujuan (Intrilligator, 1978). Variabel keputusan optimasi pola tanam yaitu tipe, lokasi, dan luasan penggunaan lahan yang didasarkan pada pola dan tipe penggunaan lahan aktual.

Penggunaan program linear ini menggunakan tabel simpleks karena memiliki lebih dari dua variabel. Metode simpleks merupakan prosedur perhitungan yang bersifat iteratif, yaitu bergerak selangkah demi selangkah dimulai dari suatu titik ekstrem pada daerah fisibel (ruang solusi) menuju ke titik ekstrem optimum. Solusi optimum (solusi basis) umumnya didapat pada titik ekstrem. Metode simpleks mengiterasikan beberapa persamaan yang mewakili fungsi tujuan dan fungsi- fungsi kendala pada program linear yang telah disesuaikan menjadi bentuk standar. Berikut adalah bentuk standar persamaan simpleks (Anwar, Nadjadji :2001) :

$$\text{Maks./min. } Z = C1.X1 + C2.X2 + \dots + Cn.Xn$$

$$\text{Pembatas : } A11.X1 + A12.X2 + \dots + A1n.Xn = b1$$

$$A21.X1 + A22.X2 + \dots + A2n.Xn = b2$$

$$Am1.X1 + Am2.X2 + \dots + Amn.Xn = bn$$

Fungsi non negatif :

$$X1, X2, X3 \dots \geq 0$$

Beberapa ketentuan yang perlu diperhatikan dalam penyelesaian metode simpleks:

1. Nilai kanan fungsi tujuan harus nol (0).
2. Nilai kanan fungsi kendala harus positif. Apabila negatif, nilai tersebut harus dikali dengan -1.
3. Fungsi kendala dengan tanda " \leq " harus diubah ke bentuk " $=$ " dengan menambahkan variabel slack/surplus. Variabel slack/surplus disebut juga variabel dasar. Penambahan slack variable menyatakan kapasitas yang tidak digunakan atau tersisa pada sumber daya tersebut. Hal ini karena ada kemungkinan kapasitas yang tersedia tidak semua digunakan dalam proses produksi.
4. Fungsi kendala dengan tanda " \geq " diubah ke bentuk " \leq " dengan cara mengkalikan dengan -1, lalu diubah ke bentuk persamaan ($=$) dengan ditambah variabel slack. Kemudian karena nilai kanan negatif, dikalikan lagi dengan -1 dan ditambah artificial variable (M). Artificial variable ini secara fisik tidak mempunyai arti, dan hanya digunakan untuk kepentingan perhitungan saja.
5. Fungsi kendala dengan tanda " $=$ " harus ditambah artificial variable (M). (Dian, Wirdasari: 2009). Untuk tahap selanjutnya akan dilakukan dengan cara iterasi. Langkah- langkah untuk satu kali iterasi untuk menghasilkan nilai maksimal dapat dilakukan dari tabel simpleks sebagai berikut :

1. Cari diantara nilai c_1 pada baris fungsi tujuan (baris ke-0) yang paling bernilai positif. Angka tetapan ini adalah faktor pengali pada Variabel Non-Basis (NBV), maka variabel dengan nilai c_1 paling positif akan masuk menjadi variabel basis pada tabel simpleks berikutnya sebagai Variabel Masuk (VM).
2. Langkah ini bertujuan mencari Variabel Keluar (VK) atau diantara sejumlah variabel basis solusi (b_1) dibagi dengan angka matriks pada baris yang sama dengan b_1 dan merupakan faktor pengali dengan VM di baris tersebut. Angka perbandingan positif terkecil menentukan pada baris tersebut adalah variabel basis yang akan keluar menjadi VK.
3. Melakukan perhitungan operasi baris elementer (OBE) pada setiap baris termasuk baris fungsi tujuan sehingga didapatkan VOM sudah menjadi VBS, dan VK menjadi NBV.
4. Bila masih terdapat nilai c_1 pada baris fungsi tujuan, lanjutkan dari memulai langkah satu dan seterusnya hingga seluruh nilai c_1 menjadi nol atau positif bila keadaan terakhir terpenuhi, maka VBS adalah jawaban dari permasalahan ini dan ruas kanan pada baris fungsi tujuan adalah nilai optimum dari fungsi tujuan.

Perhitungan metode simpleks dalam studi optimasi ini menggunakan model matematika dengan tujuan yang ingin didapatkan adalah memaksimalkan hasil panen dengan percobaan alternatif pola tanam di periode yang berbeda. Sedangkan variabel yang menjadi batasan adalah debit ketersediaan air di bendung untuk irigasi.

BAB III METODOLOGI

3.1 Studi Literatur

Studi literatur adalah usaha untuk menghimpun informasi yang relevan dengan permasalahan yang akan diteliti. Informasi yang didapatkan untuk studi literatur ini diperoleh dari buku tentang optimasi pola tanam, buku hidrologi, dan sumber tertulis lain dalam bentuk cetak dan elektronik.

3.2 Survey Lapangan

Survey diperlukan untuk mengetahui letak lokasi pekerjaan, melihat secara langsung tentang permasalahan yang terjadi sebenarnya di lapangan dan kondisi jaringan. Dari hasil survey juga dapat diketahui permasalahan yang lebih mendetail. Selain itu juga dapat memberikan gambaran di lapangan secara akurat.

3.3 Pengumpulan Data

Pengumpulan data dilakukan setelah mengidentifikasi permasalahan yang ada di lapangan. Data yang digunakan dalam penulisan adalah data sekunder. Data sekunder merupakan data yang diperoleh secara tidak langsung berupa catatan maupun hasil penelitian dari pihak lain.

Adapun data-data sekunder tersebut meliputi :

- Skema Jaringan Irigasi Cau Madiun untuk mengetahui sejauh mana daerah yang menjadi tujuan suplai air irigasi dan luasannya.
- Data curah hujan selama 10 tahun terakhir, yaitu tahun 2006 sampai dengan tahun 2015 yang nantinya akan digunakan untuk mengetahui curah hujan efektif.
- Data debit inflow Kali Catur untuk mengetahui debit andalan dari Bendung Cau.
- Data klimatologi yang meliputi suhu udara rata-rata, kelembapan relatif, lamanya penyinaran matahari,

kecepatan angin yang terjadi di daerah studi. Data-data tersebut nantinya akan diolah untuk mendapatkan besarnya evapotranspirasi yang terjadi pada daerah studi.

- Data pola tanam pada daerah eksisting yang nantinya akan dijadikan acuan dalam merencanakan pola tanam yang baik.

3.4 Analisa Data dan Perhitungan

Setelah data-data yang dibutuhkan telah lengkap, maka data-data tersebut diolah untuk mendapatkan hasil yang diharapkan. Data-data yang dianalisa dan dihitung antara lain:

- Analisa hidrologi yang akan membahas perhitungan curah hujan efektif dan debit andalan.
- Evapotranspirasi yang akan menghitung besarnya evaporasi dan transpirasi yang sesuai dengan data klimatologi.
- Perencanaan pola tanam sebagai alternatif yang akan diambil guna mencapai suatu kondisi yang optimum. Dari setiap pola tanam yang diambil akan dibagi menjadi beberapa alternatif dengan masa awal tanam yang berbeda-beda. Dari setiap alternative juga akan dipecah menjadi beberapa golongan supaya kebutuhan debit puncak dapat dikurangi.
- Analisa kebutuhan air dari tiap-tiap alternatif pola tanam yang disajikan. Ada beberapa hal yang mempengaruhi besarnya kebutuhan air yang diperlukan, yakni jenis tanaman, besarnya perkolasi yang terjadi di lapangan, efisiensi irigasi dan evapotranspirasi.

3.5 Optimasi Pola Tanam Dengan *Linear Programming*

Tujuan dari optimasi pola tanam adalah menentukan keuntungan maksimal hasil panen yang dapat dihasilkan suatu lahan dengan jenis tanaman yang berbeda. Optimasi pola tanam menggunakan Quantity Methods for Windows – Linear

Programming. Jika hasil optimasi lebih minimal daripada kondisi intensitas tanam eksisting, maka percobaan perhitungan dilakukan kembali pada bagian pola tanam, lalu dilakukan optimasi dengan menggunakan Linear Programming pada tiap-tiap alternatif pola tanam hingga pola tanam menunjukkan nilai optimum. Berikut adalah alur pengerjaan optimasi menggunakan *POM-QM Linear Programming*.

3.6 Analisa Hasil Optimasi

Tahapan ini untuk mendapatkan hasil yang paling optimum dan dapat diketahui besarnya produksi hasil tani yang didapat berdasarkan pada analisa pola tanam yang paling maksimal.

3.7 Intensitas Tanaman

Intensitas tanam adalah perbandingan antara luas tanam per tahun dengan luas lahan. Semakin luas area tanam yang diairi, maka kebutuhan air irigasi semakin besar. Hasil intensitas tanam didapatkan setelah melakukan percobaan perhitungan dengan menggunakan Linear Programming.

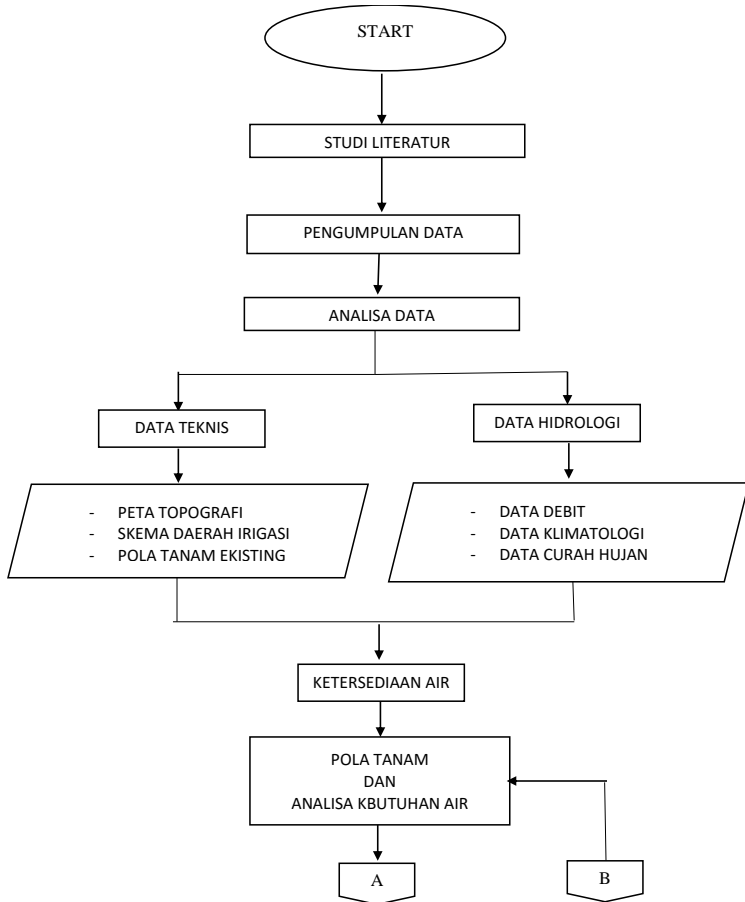

3.8 Keuntungan Hasil Produksi

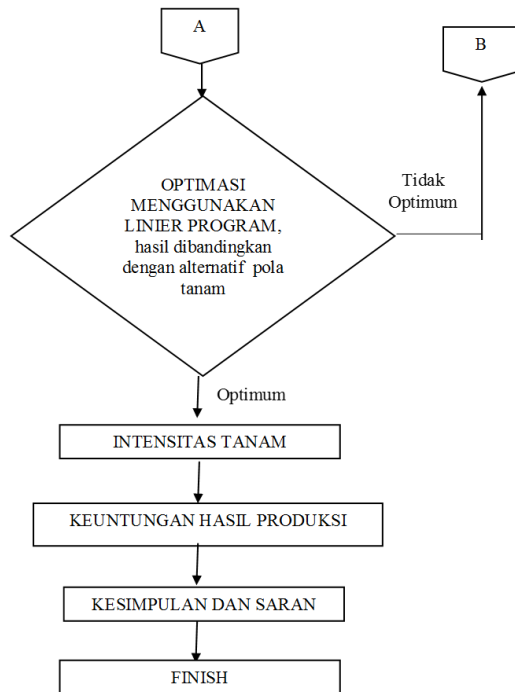

Setelah mengetahui luas lahan dan intensitas tanam yang paling optimal dari hasil model optimasi program linear, dapat diketahui keuntungan hasil produksi berdasarkan ketetapan harga hasil panen.

3.9 Kesimpulan

Penarikan kesimpulan dilakukan setelah mendapatkan hasil perhitungan optimasi menggunakan Linier Programming yang dibandingkan dengan alternatif model optimasi lain. Hasil optimasi harus menunjukkan nilai intensitas tanam yang lebih optimum daripada intensitas tanam yang dihasilkan pola tanam alternatif lainnya, sehingga studi ini menghasilkan pola tanam yang baru.

BAB IV

HASIL PERHITUNGAN

4.1 ANALISA HITUNGAN

4.1.1 KLIMATOLOGI

Analisis klimatologi akan menghasilkan perhitungan evapotranspirasi yang dilakukan dengan menggunakan metode Penman modifikasi. Perhitungan evapotranspirasi dengan menggunakan metode Penman modifikasi memerlukan data temperatur udara, kelembapan relatif, kecepatan udara, lama penyinaran matahari, dan kecepatan angin suatu daerah untuk dapat menentukan nilai evapotranspirasi.

Dalam perhitungan ini, data klimatologi yang digunakan adalah merupakan rata-rata data selama 5 tahun dari tahun 2012 sampai tahun 2016. Berikut adalah contoh perhitungan evapotranspirasi pada bulan Januari.

Data klimatologi bulan Januari :

- 1) Suhu rata-rata (T) = $24,98^{\circ}\text{C}$
- 2) Lama penyinaran matahari (n) = $46,86\%$
- 3) Kelembapan relatif (RH) = $99,48\%$
- 4) Kecepatan angin (u) = $23,27\text{ km/hari} = 0,27\text{ m/s}$

1. Perhitungan

- 1) Mencari tekanan uap jenuh, e_a (mbar)
Diketahui $T = 24,98^{\circ}\text{C}$
Maka $e_a = 31,70\text{ mbar}$
- 2) Menghitung tekanan uap nyata, e_d (mbar)
 $E_d = e_a \times RH = 31,70 \times 99,48\% = 31,54\text{ mbar}$.
- 3) Menghitung perbedaan tekanan uap, $e_a - e_d$ (mbar)

- $(e_a - e_d) = 31,70 - 31,54 = 0,16 \text{ mbar.}$
- 4) Menghitung fungsi angin, $f(u)$ (km/hari)
 Diketahui $U = 0,27 \text{ m/s}$
 $F(u) = 0,27 \times (1 + (0,27 \times 0,864)) = 0,33 \text{ km/hari}$
 - 5) Mencari faktor W
 Diketahui $T = 24,98 ^\circ\text{C}$,
 Maka $W = 0,74$
 - 6) Mencari faktor pembobot $(1-W)$
 Maka $(1-W) = 0,26$
 - 7) Mencari radiasi ekstra terrestrial, R_a (mm/hari)
 Lokasi stasiun klimatologi berada pada koordinat $7^\circ 38' 30'' \text{ LS} - 111^\circ 20' 30'' \text{ BT}$
 Maka $R_a = 15,95 \text{ mm/hari}$
 - 8) Menghitung radiasi netto gelombang pendek, R_s (mm/hari)
 $R_s = ((0,25 + 0,5 \times (n/N)) \times R_a$
 $R_s = ((0,25 + 0,5 \times (0,46)) \times 15,95 = 7,72 \text{ mm/hari}$
 - 9) Menghitung radiasi netto gelombang pendek, R_{ns} (mm/hari)
 $R_{ns} = R_s (1 - \alpha) ; \alpha = 0,25 \text{ (koef. permukaan air)}$
 $R_{ns} = 7,72 (1 - 0,25) = 5,79 \text{ mm/hari}$
 - 10) Mencari fungsi tekanan uap nyata $f(e_d)$
 Diketahui $e_d = 31,54 \text{ mbar}$,
 Maka $f(e_d) = 0,09$
 - 11) Mencari fungsi penyinaran, $f(n/N)$
 Diketahui $(n/N) = 0,47$
 Maka $f(n/N) = 0,52$
 - 12) Mencari fungsi suhu, $f(T)$
 Diketahui $T = 24,98 ^\circ\text{C}$
 Maka $f(T) = 15,70$
 - 13) Menghitung radiasi netto gelombang panjang, R_{nl}
 $R_{nl} = f(e_d) \times f(n/N) \times f(T)$
 $R_{nl} = 0,09 \times 0,52 \times 15,70 = 0,76 \text{ mm/hari}$
 - 14) Menghitung radiasi netto, R_n
 $R_n = R_{ns} - R_{nl} = 5,79 - 0,76 = 5,03 \text{ mm/hari}$
 - 15) Mencari faktor koreksi, c

Diketahui $R_s = 7,72 \text{ mm/hari}$

Maka $c = 0,763$

16) Menghitung evapotranspirasi potensial, E_{to} (mm/hari)

$$E_{to} = c \{ W \cdot R_n + (1-W) \cdot f(u) \cdot (e_a - e_d) \}$$

$$E_{to} = 0,763 \{ 0,74 \cdot 5,03 + (1-0,25) \cdot 0,33 \cdot (31,70 - 31,54) \} = 2,86 \text{ mm/hari}$$

Perhitungan evapotranspirasi potensial rata-rata selama lima tahun ditunjukkan oleh tabel 4.1 berikut

Tabel 4.1 Data Klimatologi dan Perhitungan Evapotranspirasi Potensial

| No | Data Bulanan | Satuan | Jan | Feb | Mar | Apr | Mei | Jun | Jul | Agt | Sep | Okt | Nov | Des |

(Sumber : Hasil Perhitungan)

4.1.2 Perhitungan Debit Andalan

Dalam pengerjaan Tugas Akhir ini, perhitungan debit andalan berdasarkan data debit yang tersedia dari hasil pengukuran di lapangan pada tahun 2006 sampai tahun 2015. Untuk keperluan irigasi ditetapkan debit andalan sebesar 80%. Hal ini berarti adanya kegagalan atau debit-debit yang lebih kecil dari debit andalan sebesar 20%. Sehingga didapatkan besarnya debit yang sesuai untuk keperluan irigasi.

| | |
|--------------|---|
| Q80% | = Rangking debit dari yang terbesar yang nomor ke m |
| Probabilitas | = $(m/(n+1)) \times 100\%$ |
| n | = Total pengamatan selama T tahun |
| m | = Nomer urut |

Contoh perhitungan debit andalan untuk bulan Januari periode pertama :

1. Mengurutkan data debit intake bulanan dari data terbesar sampai terkecil pada tahun 2006 sampai tahun 2015.
2. Untuk menentukan besarnya debit andalan dengan peluang 80%, digunakan probabilitas dengan Metode Weibull berikut :

$$P = \frac{m}{n+1} \times 100\%$$

Keterangan :

| | |
|---|-------------------|
| P | : Peluang (%) |
| m | : Nomer urut data |
| n | : Jumlah data |

$P = \frac{0,2}{10+1} \times 100\% = 20\%$, maka peringkat 2 terbawah pada tabel tidak terpenuhi.

3. Dari data yang telah diurutkan, didapatkan dua peringkat terbawah yang tidak memenuhi batas minimal debit intake, maka dilakukan interpolasi antara peringkat ketiga dari bawah dan peringkat kedua dari bawah.

Hasil perhitungan debit andalan selama sepuluh tahun ditunjukkan pada tabel 4.2

Tabel 4.2 Rekap Perhitungan Debit Andalan

| | | Peringkat | BULAN (l/dt) | | | | | | | | | | | | | | | | | |

4.2 Analisa Kebutuhan Air Untuk Irigasi

Analisa kebutuhan air irigasi adalah salah satu tahap penting yang diperlukan dalam perencanaan dan pengelolaan sistem irigasi. Kebutuhan air tanaman didefinisikan sebagai jumlah air yang dibutuhkan oleh tanaman pada suatu periode untuk dapat tumbuh dan berproduksi. Kebutuhan air untuk area pertanian meliputi evapotranspirasi, penyiapan lahan pertanian, penggantian air, serta kehilangan selama pemakaian. Perhitungan curah hujan dilakukan untuk mengetahui kebutuhan air tanaman padi, tebu, dan palawija.

Contoh perhitungan kebutuhan air untuk tanaman padi, tebu dan palawija pada bulan Januari periode 1:

Tanaman Padi :

1. Menghitung evapotranspirasi
 $E_{to} = 2,86 \text{ mm/hari}$
2. Perkolasi
 Berdasarkan tekstur tanah lempung berliat dengan permeabilitas sedang yang dapat dipakai berkisar 2 sampai 2,5 mm/hari, maka nilai perkolasi sebesar 2 mm/hari.
3. Persiapan lahan
 $IRR = 12,79 \text{ mm/hari}$
4. Hujan Efektif
 $R_{80} = 6,67 \text{ mm/hari}$
 $R_{e \text{ padi}} = 0,47 \text{ mm/hari}$
5. Penggantian lapisan air
 $WLR = \frac{50 \text{ mm}}{30 \text{ hari}} = 1,667 \text{ mm/hari}$
6. Koefisien Tanaman
 $C1 \text{ padi unggul} = 0,95$
 $C2 \text{ padi unggul} = 1,05$

C3 padi unggul = 1,04

C rata-rata dari padi unggul pada Bulan Januari Periode 1 sebesar 1,01

7. Penggunaan Konsumtif, Etc

Eto x C rata-rata = 2,90 mm/hari

8. Kebutuhan air untuk tanaman, NFR.

Padi = Etc + P – Re + WLR
 = 6,13 + 2 – 0,47 + 1,667
 = 6,10 mm/hari
 = 0,71 l/dt/ha

9. Efisiensi Irigasi

Merupakan besarnya kehilangan air pada saluran primer (80%), saluran sekunder (90%), dan saluran tersier (90%).

$$EI = 80\% \times 90\% \times 90\% = 65\%$$

10. Kebutuhan air di pintu pengambilan, DR

DR = NFR/EI (l/dt/ha)

DR padi = 0,71/0,65 = 1,09 l/dt/ha

Tanaman Tebu :

1. Menghitung evapotranspirasi

Eto = 2,86 mm/hari

2. Perkolasi

Berdasarkan tekstur tanah lempung berliat dengan permeabilitas sedang yang dapat dipakai berkisar 2 sampai 2,5 mm/hari, maka nilai perkolasi sebesar 2 mm/hari.

3. Persiapan Lahan

IRR = 12,79 mm/hari

4. Hujan Efektif

R80 : 6,67 mm/hari

R_{tebu} : 0,14 mm/hari

5. Koefisien Tanaman

C1 tebu = 1,05

C2 tebu = 1,05

C3 tebu = 1,05

C rata-rata dari tebu pada Bulan Januari Periode 1 sebesar 1,05

6. Penggunaan Konsumtif, Etc

Eto x C rata-rata = 3,00 mm/hari

7. Kebutuhan air untuk tanaman, NFR.

Tebu = Etc + P – Re tabu

= 3,00 + 2 – 0,16

= 4.86 mm/hari

= 0,56 l/dt/ha

8. Efisiensi Irigasi

Merupakan besarnya kehilangan air pada saluran primer (80%), saluran sekunder (90%), dan saluran tersier (90%).

EI = 80% x 90% x 90% = 65%

9. Kebutuhan air di pintu pengambilan, DR

DR = NFR/EI (l/dt/ha)

DR padi = 0,56/0,65 = 0,87 l/dt/ha

Tanaman Palawija :

1. Menghitung evapotranspirasi

Eto = 2,86 mm/hari

2. Perkolasi

Berdasarkan tekstur tanah lempung berliat dengan permeabilitas sedang yang dapat dipakai berkisar 2 sampai 2,5 mm/hari, maka nilai perkolasi sebesar 2 mm/hari.

3. Persiapan Lahan

IRR = 12,79 mm/hari

4. Hujan Efektif

R80 : 6,67 mm/hari

Rpalawija : 0,15 mm/hari

5. Koefisien Tanaman

C1 palawija = 1,02

C2 palawija = 1,05

- C3 palawija = 1,01
 C rata-rata dari palawija pada Bulan Januari
 Periode 1 sebesar 1,03
6. Penggunaan Konsumtif, Etc
 $Eto \times C \text{ rata-rata} = 2,93 \text{ mm/hari}$
 7. Kebutuhan air untuk tanaman, NFR
 $\text{Palawija} = Etc + P - Re \text{ palawija}$
 $= 2,93 + 2 - 0,15$
 $= 4,79 \text{ mm/hari}$
 $= 0,55 \text{ l/dt/ha}$
 8. Efisiensi Irigasi
 Merupakan besarnya kehilangan air pada saluran primer (80%), saluran sekunder (90%), dan saluran tersier (90%).
 $EI = 80\% \times 90\% \times 90\% = 65\%$
 9. Kebutuhan air di pintu pengambilan, DR
 $DR = NFR/EI \text{ (l/dt/ha)}$
 $DR \text{ padi} = 0,55/0,65 = 0,85 \text{ l/dt/ha}$

4.2.1 Perhitungan Curah Hujan DAS

Data curah hujan rata-rata DAS Catur didapatkan dari data sekunder berdasarkan metode Poligon Thiessen. Berikut adalah gambar stasiun hujan pada DAS Catur (Gambar 4.1) dan tabel keterangan stasiun hujan (Tabel 4.3).

Gambar 4. 1 Stasiun Hujan pada DAS Catur
(Sumber: UPT PSAWS Madiun, 2017)

Tabel 4.3 Luas Daerah Pengaruh dengan Metode Poligon Thiessen

| No | Nama Stasiun | Koef.Thiessen |
|----|---------------|---------------|
| 1 | Sta. Dungus | 42.23% |
| 2 | Sta. Kanigoro | 45.51% |
| 3 | Sta. Cau | 12.26% |
| | | Jumlah = 100% |

(Sumber: Hasil Perhitungan)

4.2.2 Perhitungan Curah Hujan Efektif

Curah hujan efektif adalah curah hujan yang jatuh ke permukaan suatu daerah dan dapat digunakan tanaman untuk pertumbuhannya dalam memenuhi kehilangan air akibat evapotranspirasi, perkolasi, dan lain – lain. Berikut adalah contoh perhitungan curah hujan efektif pada Bulan Januari periode 1.

1. Mengurutkan data curah hujan tahun 2006 sampai tahun 2015 (Tabel 4.4) dari urutan terbesar hingga terkecil.

2. Menghitung curah hujan dengan peluang keandalan 80%.
 $R_{80} = (n/5) + 1$; $n = \text{jumlah data} = 10$
 $R_{80} = (10/5) + 1 = 3$
3. Dari data curah hujan yang telah diurutkan didapatkan tiga peringkat terbawah sebagai R_{80} -nya.
(Tabel 4.5)

Tabel 4.4 Data Curah Hujan Tahun 2006-2015

| Tahun | Bulan (mm) | | | | | | | | | | | | | | | | | |

4.2.2.1 Curah Hujan Efektif Untuk Tanaman Padi

Besar curah hujan efektif untuk tanaman padi ditentukan dengan 80% dari curah hujan rata-rata tengah bulan dengan kegagalan 20% (dari curah hujan 80%). Apabila data hujan dipergunakan 10 harian, maka Re untuk tanaman jenis padi dapat dicari dengan menggunakan rumus :

$$Re_{\text{padi}} = (R_{80} \times 70\%) / 10 \dots \dots \dots (2.16)$$

Hasil perhitungan curah hujan efektif untuk tanaman padi dapat ditunjukkan pada tabel 4.6, perhitungan curah hujan efektif untuk tanaman palawija dapat ditunjukkan pada tabel 4.7 dan untuk perhitungan curah hujan efektif untuk tanaman tebu dapat ditunjukkan pada tabel 4.6.

(Sumber : Hasil Perhitungan)

Berikut adalah penjelasan perhitungan Tabel 4.8 untuk tanaman tebu :

1. Kolom (1) : Bulan
2. Kolom (2) : Periode 10 harian

3. Kolom (3) : Curah hujan efektif untuk tanaman padi (mm/10 hari)
4. Kolom (4) : Curah hujan efektif untuk tanaman tebu = 60% x kolom (3), (mm/10hari)
5. Kolom (5) : Jumlah curah hujan efektif untuk tanaman tebu dalam satu bulan = jumlah kolom (4) (mm/bln)
6. Kolom (6) : Evapotranspirasi potensial, (mm/bln)
7. Kolom (7) : $f_D = 0,53 + (0,00016 \times 10^{-5} \times D^2) + (2,32 \times 10^{-7} \times D^3)$, (D : kedalaman muka air tanah yang diperlukan)
8. Kolom (8) : $Re \text{ tebu} = f_D \times (1,25 \times R50^{0,824} - 2,29) \times 10^{0,00095 \times ETo}$, (mm/bulan)
9. Kolom (9) : $Re \text{ tebu dalam satu periode} = \text{kolom (8)}/3$, (mm/10hr)

4.2.3 Perhitungan Kebutuhan Air Untuk Penyiapan Lahan

Kebutuhan air untuk penyiapan lahan dipengaruhi oleh perkolasi dan evapotranspirasi. Analisis kebutuhan air selama pengolahan lahan dapat menggunakan metode Van de Goor dan Zijlstra (1968), berikut adalah contoh perhitungan kebutuhan air untuk penyiapan lahan pada Bulan Januari :

1. Evapotranspirasi Potensial, $Eto = 2,86 \text{ mm/hari}$
2. Evaporasi air terbuka, Eo .
 $Eo = 1,1 \times ETo = 1,1 \times 2,86 = 3,15 \text{ mm/hari}$
3. Perkolasi, $P = 2 \text{ mm/hari}$
4. Kebutuhan air untuk mengganti kehilangan air akibat evaporasi dan perkolasi di sawah yang sudah dijenuhkan M.
 $M = Eo + P = 3,15 + 2 = 5,15 \text{ mm/hari}$
5. Jangka waktu penyiapan, $T = 30 \text{ hari}$.
6. Kebutuhan air yang dibutuhkan untuk penjenuhan, S.
 $S = 300 \text{ mm}$.

$$7. \text{ Konsta, } k = \frac{M \times T}{S} = \frac{5,15 \times 30}{300} = 0,51$$

8. Kebutuhan air untuk pengolahan lahan, IR.
Bilangan eksponen, $e = 2,7182$

$$IR = M \times \frac{e^k}{e^k - 1} = 5,15 \times \frac{2,7182^{0,45}}{2,7182^{0,45} - 1} = 12,79 \text{ mm/hari}$$

Jadi, kebutuhan air untuk penyiapan lahan adalah sebesar 12,79 mm/hari. Berikut adalah tabel hasil perhitungan kebutuhan air untuk penyiapan lahan.

Tabel 4.9 Perhitungan Kebutuhan Air Untuk Penyiapan Lahan

| No | Parameter | Satuan | Bulan | | | | | | | | | |

(Sumber : Hasil Perhitungan)

4.2.4 Perhitungan Perencanaan Pola Tanam

Kebutuhan air untuk tanaman di sawah ditentukan oleh evapotranspirasi, jenis tanah, jenis varietas padi dan palawija, dan analisis curah hujan efektif. Pemberian jumlah air yang tepat akan menghasilkan hasil panen yang optimal pada tanaman di lahan irigasi.

Kebutuhan air konsumtif tanaman dipengaruhi oleh jenis dan usia tanaman. Pada saat tanaman mulai tumbuh, nilai kebutuhan air konsumtif meningkat sesuai pertumbuhannya dan mencapai maksimum pada saat pertumbuhan vegetasi maksimum. Setelah mencapai maksimum dan berlangsung beberapa saat menurut jenis tanaman, nilai kebutuhan air konsumtif akan menurun sejalan dengan pematangan biji. Tujuan dari analisis kebutuhan air untuk tanaman adalah untuk mengetahui luas lahan

yang direncanakan untuk tanaman padi dan palawija berkaitan dengan jumlah air yang tersedia. Agar pemberian air dapat dibagikan secara optimal, maka diperlukan pengauran pola tanam dan jadwal awal tanam yang tepat.

Musim tanam yang digunakan dalam perencanaan pola tanam ini adalah sebagai berikut:

1. Musim tanam hujan : November-Februari
2. Musim tanam kemarau I : Maret-Juni
3. Musim tanam kemarau II : Juli-Oktober

Alternatif pola tanam yang digunakan sebagai berikut :

1. Alternatif 1 : Awal tanam bulan November 1
2. Alternatif 2 : Awal tanam bulan November II
3. Alternatif 3 : Awal tanam bulan November III
4. Alternatif 4 : Awal tanam bulan Desember I
5. Alternatif 5 : Awal tanam bulan Desember II
6. Alternatif 6 : Awal tanam bulan Desember III

Berikut adalah contoh perhitungan dan penjelasan alternatif pola tanam 6 dengan masa awal tanam Bulan Desember 3 pada tabel 4.10 dan penjelasan alternative pola tanam 2 dengan masa awal tanam Bulan November 2 pada tabel 4.11. Perhitungan Alternatif Pola Tanam 1-5 terdapat pada lampiran B.

Tabel 4.11 Perhitungan Alternatif Pola Tanam 2

[illegible]

(Sumber : Hasil Perhitungan)

Berikut adalah penjelasan Tabel 4.10 dan Tabel 4.11 :

1. Kolom (1) dan (2) : Bulan dan Periode
2. Kolom (3) : Evapotranspirasi potensial, E_{to} (mm/hari). Perhitungan E_{to} terdapat pada tabel
3. Kolom (4) : Perkolasi, $P = 2\text{mm/hari}$
4. Kolom (5) : Curah hujan efektif untuk tanaman padi, Re_{padi} (mm/hari). Perhitungan Re_{padi} terdapat pada Tabel
5. Kolom (6) : Penggantian lapisan air 1,667 mm/hari selama per 10 hari, WLR (mm/hari)
6. Kolom (7), (8), (9) : Koefisien tanaman padi, kc_1 , kc_2 , kc_3 .
7. Kolom (10) : Koefisien rata-rata tanaman padi, kc .
8. Kolom (11) : Evapotranspirasi tanaman, E_{Tc} .
 $E_{Tc} = E_{to} \times c$ (mm/hari)
9. Kolom (12) : Kebutuhan air untuk tanaman padi,
 $NFR = E_{Tc} + P - Re_{padi} + WLR$
 Keterangan :
 $NFR = \text{Net Field Requirement}$ (Kebutuhan air di sawah) (mm/hari)
 $E_{Tc} = E_{to} \times c$ (mm/hari)
 $P = \text{Perkolasi}$ (mm/hari)
 $Re_{padi} = \text{Curah hujan efektif tanaman padi}$ (mm/hari)
 $WLR = \text{Water Layer Requirement}$ (Pergantian Lapisan Air) (mm/hari)
10. Kolom (13) : Konfigurasi satuan NFR (liter/detik/Ha) = Kolom (12)/ $(24 \times 3600 \times 10^{-4})$
11. Kolom (14) : Kebutuhan air untuk irigasi di pintu pengambilan, DR (diversion requirement) (l/dt/ha).
 $DR = \frac{NFR}{EI}$
 Keterangan :
 $DR = \text{Diversion Requirement}$ (l/dt/ha)

NFR = *Net Field Requirement* (Kebutuhan air di sawah) (l/dt/ha)

EI = Efisiensi irigasi. Besarnya kehilangan air pada saluran primer (80%), sekunder (90%), dan tersier (90%).

$$EI = 80\% \times 90\% \times 90\% = 65\%.$$

12. Kolom (15) : Curah hujan efektif untuk tanaman palawija, Re_{palawija} (mm/hari). Perhitungan Re_{palawija} terdapat pada tabel 5....
13. Kolom (16), (17), (18) : Koefisien tanaman palawija, kc_1 , kc_2 , dan kc_3
14. Kolom (19) : Koefisien rata-rata tanaman palawija, kc .
15. Kolom (20) : Evapotranspirasi tanaman palawija, (mm/hari). $ET_c = E_{To} \times kc$
16. Kolom (21) : Kebutuhan air untuk tanaman palawija,

$$NFR = ET_c + P - Re_{\text{palawija}}$$

Keterangan :

NFR = *Net Field Requirement* (Kebutuhan air di sawah) (mm/hari).

$$ET_c = E_{To} \times kc \text{ (mm/hari)}$$

P = Perkolasi (mm/hari)

Re_{palawija} = curah hujan efektif tanaman palawija (mm/hari)

17. Kolom (22) : Konfigurasi satuan NFR (liter/detik/Ha) = Kolom (21) / (24 x 3600 x 10^{-4}).
18. Kolom (23) : Kebutuhan air untuk irigasi di pintu pengambilan, DR (*diversion requirement*) (l/dt/Ha).

$$DR = \frac{NFR}{EI}$$

Keterangan :

DR = *Diversion Requirement* (l/dt/ha)

NFR = *Net Field Requirement* (kebutuhan air di sawah) (l/dt/ha)

- EI = Efisiensi irigasi. Besarnya kehilangan air pada saluran primer (80%), sekunder (90%), dan tersier (90).
 $EI = 90\% \times 90\% \times 90\% = 65\%$.
19. Kolom (24) : Curah hujan efektif untuk tanaman tebu, Re_{tebu} (mm/hari). Perhitungan Re_{tebu} terdapat pada tabel 5....
 20. Kolom (25), (26), (27) : Koefisien tanaman tebu, kc_1 , kc_2 , dan kc_3
 21. Kolom (28) : Koefisien rata-rata tanaman tebu, kc .
 22. Kolom (29) : Evapotranspirasi tanaman tebu, (mm/hari). $ET_c = ET_o \times kc$
 23. Kolom (30) : Kebutuhan air untuk tanaman palawija,
 $NFR = ET_c + P - Re_{tebu}$
 Keterangan :
 NFR = Net Field Requirement (Kebutuhan air di sawah) (mm/hari).
 $ET_c = ET_o \times kc$ (mm/hari)
 P = Perkolasi (mm/hari)
 $Re_{palawija}$ = curah hujan efektif tanaman tebu (mm/hari)
 24. Kolom (31) : Konfigurasi satuan NFR (liter/detik/Ha) = Kolom (30)/ (24 x 3600 x 10⁻⁴).
 25. Kolom (32) : Kebutuhan air untuk irigasi di pintu pengambilan, DR (diversion requirement) (l/dt/Ha).
 $DR = NFR/EI$
 Keterangan :
 DR = Diversion Requirement (l/dt/ha)
 NFR = Net Field Requirement (kebutuhan air di sawah) (l/dt/ha)
 EI = Efisiensi irigasi. Besarnya kehilangan air pada saluran primer (80%), sekunder (90%), dan tersier (90).
 $EI = 90\% \times 90\% \times 90\% = 65\%$.

4.3 Optimasi Air Bendung Untuk Irigasi

Dengan terbatasnya jumlah ketersediaan air di bendung, dilakukan permodelan optimasi agar pemanfaatan air untuk irigasi dapat menghasilkan luas lahan yang optimal untuk penanaman sehingga menghasilkan panen yang maksimal. Optimasi yang dilakukan berupa pemilihan keputusan dari berbagai alternatif yang telah diperhitungkan berdasarkan kebutuhan air tanaman. Digunakan program aplikasi POMQM for Windows untuk membantu dalam pengoptimasian air dari bendung untuk irigasi. Model matematis dalam analisis optimasi ini adalah:

1. Variabel keputusan, adalah variabel yang nilainya akan dicari. Dalam perhitungan ini, variabel keputusan adalah luas lahan dan harga hasil panen.
2. Fungsi tujuan, merupakan suatu rumusan penentu koefisien dari variabel keputusan dan bertujuan untuk memaksimalkan hasil. Fungsi tujuan dalam perhitungan ini adalah memaksimalkan pembagian luas lahan untuk tanaman yang dapat untuk menghasilkan keuntungan hasil panen.
3. Fungsi kendala, merupakan persamaan yang menggunakan jumlah ketersediaan sumber daya sebagai pembatas. Dalam perhitungan ini, fungsi kendala adalah jumlah ketersediaan air di waduk dan luas lahan total.
4. Kendala Non-negatif, setiap keputusan (kuantitatif) yang diambil tidak boleh mempunyai nilai negatif.

Berikut ini adalah persamaan-persamaan dalam model optimasi:

1. Fungsi tujuan:
Maksimalkan $Z = X_1 + Y_1 + X_2 + Y_2 + X_3 + Y_3$
2. Fungsi kendala:
 - Debit andalan:
 - $X_1 + Y_1 \leq Q_a$ (a = periode MT1)
 - $X_2 + Y_2 \leq Q_b$ (b = periode MT2)
 - $X_3 + Y_3 \leq Q_c$ (c = periode MT3)

- Luas Lahan Irigasi:

$$X1 + Y1 \leq A_{total}$$

$$X2 + Y2 \leq A_{total}$$

$$X3 + Y3 \leq A_{total}$$

- *Non- Negativity*

$$X1, Y1, X2, Y2, X3, Y3 \geq 0$$

Keterangan:

X1 : luas lahan untuk tanaman Padi saat Musim Hujan (Ha).

X2 : luas lahan untuk tanaman Padi saat Musim Kemarau I (Ha).

X3 : luas lahan untuk tanaman Padi saat Musim Kemarau II (Ha).

Y1 : luas lahan untuk tanaman Palawija saat Musim Hujan (Ha).

Y2 : luas lahan untuk tanaman Palawija saat Musim Kemarau I (Ha).

Y3 : luas lahan untuk tanaman Palawija saat Musim Kemarau II (Ha).

Z1 : luas lahan untuk tanaman Tebu saat Musim Hujan (Ha).

Z2 : luas lahan untuk tanaman Tebu saat Musim Kemarau I (Ha).

Z3 : luas lahan untuk tanaman Tebu saat Musim Kemarau II (Ha).

Qa, Qb, Qc : debit air kebutuhan irigasi = debit intake bendung/debit kebutuhan air irigasi (liter/detik).

Atotal : luas lahan pertanian total = 1200 Ha.

3. Jumlah variabel = 9
4. Jumlah constraints = 42

4.3.1 Analisis Data Alternatif Pola Tanam Menggunakan POM-QM

Hasil dari perhitungan Alternatif Pola Tanam 1 – 6 dimasukkan ke dalam tabel simpleks untuk dilakukan iterasi dengan menggunakan program bantu POM-QM (Gambar 4.2). Setelah memasukkan variabel, tekan “Solve” pada taskbar dan akan muncul hasil perhitungan optimasi pola tanam

Gambar 4. 5 Hasil Optimasi Keuntungan Optimum Pada Model Alternatif 6
(Sumber : Hasil Output POM QM)

Dari hasil optimasi menggunakan program bantu POM-QM, didapatkan luas lahan, intensitas tanam, dan harga hasil panen alternatif 1-6 yang ditunjukkan pada tabel 4.12

Hasil dari keuntungan produksi ekisting (Tabel 4.13) akan dibandingkan dengan dengan hasil keuntungan produksi yang telah dioptimasi pada Tabel 4.12

Sebagai hasil perbandingan, dilakukan perhitungan pola tanam eksisting dengan luas lahan dan keuntungan hasil panen sebagai berikut :

Tabel 4.13 Keuntungan Hasil Produksi Eksisting

| Tahun | Musim Tanam | Luas Lahan (Ha) | | | Intensitas Tanam (%) | | | | | | | Keuntungan (Rp) | | |
|-----------|-----------------|-----------------|------|----------|----------------------|------|----------|-------|-------|----------|-------|-------------------|----------------------|----------------------|

(Sumber : Hasil Optimasi POM-QM dan Hasil Perhitungan)

Berikut adalah penjelasan perhitungan Tabel 4.12 :

1. Kolom(1) : alternatif.
2. Kolom(2) : musim tanam (musim hujan, musim kemarau 1, dan musim kemarau 2).
3. Kolom(3) : luas lahan padi (ha).
4. Kolom(4) : luas lahan tebu (ha.)
5. Kolom(5) : luas lahan palawija (ha)
6. Kolom(6) : intensitas tanam padi tiap musim tanam (%).
7. Kolom(7) : intensitas tanam tebu tiap musim tanam (%).
8. Kolom(8) : intensitas tanam palawija tiap musim tanam (%).
9. Kolom(9) : intensitas tanam padi kumulatif (%).
10. Kolom(10) : intensitas tanam tebu kumulatif (%).
11. Kolom(11) : intensitas tanam palawija kumulatif (%).
12. Kolom(12) : total intensitas tanam padi, tebu dan palawija = 252.10%.
13. Kolom(13) : harga padi Rp = 10.000/kg.
Harga padi = 10.000 x total luas kolom (3) (Rp).
14. Kolom(14) : harga tebu Rp = 12.500/kg.
Harga tebu = 12.500 x total luas kolom (4) (Rp).
15. Kolom(15) : harga palawija Rp = 3.800/kg.
Harga palawija = 3.800 x total luas kolom (5) (Rp).
16. Kolom(16) : harga total = kolom (13) + kolom (14) + kolom (15) (Rp).

Dari perhitungan Tabel 4.12, berdasarkan luas lahan dan harga hasil panen dipilih Alternatif 6 dengan masa tanam Desember 3 yang menghasilkan harga hasil panen paling optimal dan lebih menguntungkan dari keuntungan eksisting. Tetapi pada hasil perhitungan alternatif 6 dengan masa tanam Desember 3 berdasarkan luas lahan tersebut didapatkan banyak nilai 0 pada musim hujan untuk jenis tanaman padi yang dikarenakan kurangnya ketersediaan air dan lebih banyak nilai pada tanaman jenis palawija maka dari itu perlu dilakukan *trial and error* (Gambar 4.6) dengan batasan palawija dan tebu agar nilai jenis tanaman padi mendapatkan nilai tanam.

Gambar 4.6 Model Optimasi Alternatif Pola Tanam 2 untuk Luas Optimum Masa Tanam November Periode 2
(Sumber: Hasil Output POM QM)

Dari gambar di atas, nilai yang dimasukkan sebagai variabel adalah nilai diversion requirement yang telah dihitung pada Tabel 4.11. Sedangkan yang menjadi variabel batasan adalah debit andalan dan luas lahan irigasi total.

Gambar 4.7 Hasil Model Optimasi Alternatif Pola Tanam 2 untuk Luas Lahan Optimum Masa Tanam November 2 (Sumber : Hasil Output POM QM)

Hasil optimasi untuk Alternatif Pola Tanam 1-5 menggunakan POM QM terdapat pada lampiran B.

Setelah mengetahui luas lahan optimal, dicari hasil keuntungan maksimal dengan mengganti variabel tujuan menjadi harga hasil panen tiap satu hektar lahan seperti pada Gambar 4.8 berikut.

Gambar 4.9 Hasil Optimasi Keuntungan Optimum Pada Model Alternatif 2 Dengan Masa Tanam November 2
(Sumber : Hasil Output POM QM)

Dari hasil optimasi menggunakan program bantu POM-QM, didapatkan luas lahan, intensitas tanam, dan harga hasil panen alternatif 1-6 yang ditunjukkan pada tabel 4.14

Sebagai hasil perbandingan, dilakukan perhitungan pola tanam eksisting dengan luas lahan dan keuntungan hasil panen sebagai berikut :

(Sumber : Hasil Optimasi POM-QM dan Hasil Perhitungan)

Berikut adalah penjelasan Tabel 4.14 :

1. Kolom(1) : alternatif.
2. Kolom(2) : musim tanam (musim hujan, musim kemarau 1, dan musim kemarau 2).
3. Kolom(3) : luas lahan padi (ha).
4. Kolom(4) : luas lahan tebu (ha.)
5. Kolom(5) : luas lahan palawija (ha)
6. Kolom(6) : intensitas tanam padi tiap musim tanam (%).
7. Kolom(7) : intensitas tanam tebu tiap musim tanam (%).
8. Kolom(8) : intensitas tanam palawija tiap musim tanam (%).
9. Kolom(9) : intensitas tanam padi kumulatif (%).
10. Kolom(10) : intensitas tanam tebu kumulatif (%).
11. Kolom(11) : intensitas tanam palawija kumulatif (%).
12. Kolom(12) : total intensitas tanam padi, tebu dan palawija = 252.10%.
13. Kolom(13) : harga padi Rp = 10.000/kg.
 $\text{Harga padi} = 10.000 \times \text{total luas kolom (3) (Rp)}.$
14. Kolom(14) : harga tebu Rp = 12.500/kg.
 $\text{Harga tebu} = 12.500 \times \text{total luas kolom (4) (Rp)}.$
15. Kolom(15) : harga palawija Rp = 3.800/kg.
 $\text{Harga palawija} = 3.800 \times \text{total luas kolom (5) (Rp)}.$
16. Kolom(16) : harga total = kolom (13) + kolom (14) + kolom (15) (Rp).

Dari perhitungan Tabel 4.15, berdasarkan luas lahan dan harga hasil panen dipilih Pola Tanam Alternatif 2 dengan masa tanam November 2 yang menghasilkan harga hasil panen paling optimal yaitu sebesar Rp 50.780.913.906 dan lebih menguntungkan dari keuntungan eksistingnya yaitu sebesar Rp 42.388.230.000.

Setelah mendapatkan harga hasil panen yang paling optimal maka selanjutnya didapatkan kebutuhan air untuk tanaman padi, palawija dan tebu pada Pola Tanam Alternatif 2 dengan masa tanam November 2 (Gambar 4.10). Kemudian kebutuhan air untuk tanaman padi, palawija dan tebu pada Pola Tanam Alternatif 1-6 dapat dilihat pada lampiran B.

Gambar 4.10 Grafik Kebutuhan Air Untuk Tanaman Padi, Palawija dan Tebu Pada Pola Tanam Alternatif 2 Dengan Masa Tanam Awal November 2

BAB V

KESIMPULAN DAN SARAN

5.1 Kesimpulan

Dari hasil analisis dan perhitungan yang telah dilakukan, dapat diambil kesimpulan sebagai berikut :

1. Kondisi intensitas tanam pada Daerah Irigasi Cau berdasarkan eksistingnya kurang optimum karena presentase untuk tanaman padi, tebu, dan palawija belum mencapai 100%.

Intensitas tanam pada kondisi eksisting didapat :

- ❖ Padi : 52%
- ❖ Tebu : 27%
- ❖ Palawija : 58%
- Total : 139 %

2. Kebutuhan air irigasi untuk pola tanam tanaman padi, palawija, dan tebu pada Daerah Irigasi Cau selama 1 tahun dari tiap-tiap Alternatif Tanaman setelah dioptimasi didapatkan sebesar :

Alternatif 1 dengan Awal Masa Tanam November 1 :
0 l/dt

Alternatif 2 dengan Awal Masa Tanam November 2 :
14909,93 l/dt

Alternatif 3 dengan Awal Masa Tanam November 3 :
14119,38 l/dt

Alternatif 4 dengan Awal Masa Tanam Desember 1 :
14609,77 l/dt

Alternatif 5 dengan Awal Masa Tanam Desember 2 :
14804,04 l/dt

Alternatif 6 dengan Awal Masa Tanam Desember 3 :
15078,69 l/dt

3. Berdasarkan ketersediaan air yang ada pada Daerah Irigasi Cau, selanjutnya dilakukan analisa untuk

mengetahui besarnya luasan maksimum setiap jenis tanaman pada awal tanam mulai Nopember 1 sampai Desember 3 dengan program bantu QM for Windows 5. Dari hasil optimasi didapatkan awal tanam Nopember 2 yang paling optimal pada musim hujan memiliki intensitas tanaman sebesar 20,57%, pola tanam padi-tebu dengan luasan padi sebesar 137,86 Ha dan luasan tebu sebesar 109 Ha. Pada musim kemarau I memiliki intensitas tanaman sebesar 100%, pola tanam padi-palawija-tebu dengan luasan padi sebesar 160,42 Ha, luasan palawija sebesar 930,58 Ha dan luasan tebu sebesar 109 Ha. Pada musim kemarau II memiliki intensitas tanam sebesar 77,44%, pola tanam padi-palawija-tebu dengan luasan padi 30,24%, luasan palawija sebesar 790,06 Ha dan luasan tebu sebesar 109 Ha. Total intensitas tanaman pada awal nopember 2 sebesar 198,01 %.

4. Dari hasil luasan optimum setiap jenis tanaman dengan awal tanam mulai Nopember 1 sampai Desember 3, diperoleh pendapatan maksimum selama satu tahun. Pendapatan terbesar terdapat pada awal tanam Nopember 2 yaitu sebesar Rp 50.780.913.906. Sedangkan pendapatan terendah terdapat pada awal tanam Nopember 3 yaitu sebesar Rp 47.119.452.736. Untuk pendapatan eksisting sebesar Rp 42.388.230.000. Dengan demikian didapat peningkatan keuntungan produksi dibanding eksisting yaitu sebesar $\text{Rp } 50.780.913.906 - \text{Rp } 42.388.230.000 = \text{Rp } 8.392.683.906$.

5.2 Saran

Berikut adalah saran yang dapat diberikan setelah melakukan analisis dan perhitungan tentang optimasi Daerah Irigasi Cau Madiun :

1. Jika hasil optimasi ini akan diterapkan pada wilayah studi, maka perlu dilakukan peninjauan ulang untuk debit dalam menghitung debit yang masuk dan keluar dari bendung.
2. Untuk pihak lain yang berminat dalam meninjau lebih lanjut subjek ini dapat memperhitungkan debit intake bendung dan perhitungan data curah hujan.
3. Untuk pihak lain yang akan melakukan optimasi pada wilayah studi, diperlukan adanya koreksi ulang dalam tugas akhir ini untuk perhitungan dengan ketelitian yang baik untuk dapat menghasilkan hasil analisis yang lebih optimal.

Tabel A5 Nilai Koefisien Tanaman Tebu Dan Palawija

| Tanaman | Dalamnya akar (m) | Fraksi air yang tersedia | Air tanah yang siap pakai D(mm) | | |
|--------------|-------------------|--------------------------|---------------------------------|--------|-------|
| | | | Halus | Sedang | Kasar |
| Kedelai | 0,6 – 1,3 | 0,5 | 100 | 75 | 35 |
| Jagung | 1,0 – 1,7 | 0,6 | 120 | 80 | 40 |
| Kacang tanah | 0,5 – 1,0 | 0,4 | 80 | 55 | 25 |
| Bawang | 0,3 – 0,5 | 0,25 | 50 | 35 | 15 |
| Buncis | 0,5 – 0,7 | 0,45 | 90 | 65 | 30 |
| Kapas | 1,0 – 1,7 | 0,63 | 120 | 90 | 40 |
| Tebu | 1,2 – 2,0 | 0,65 | 130 | 90 | 40 |

Tabel A6 Nilai Perkolasi

. Nilai Perkolasi (Peresapan)

bila tidak terdapat penelitian maka dapat digunakan data sbb:

| Teksture Tanah | Perkolasi (mm/hr) |
|-------------------------------|-------------------|
| 1. Clay | 1 – 1,5 |
| 2. Silty clay | 1,5 – 2 |
| 3. Clay loan, silty clay loan | 2 – 2,5 |
| 4. Mudy clay loan | 2,5 – 3 |
| 5. Sandy loan | 3 - 5 |

Tabel A7 Rumus Kebutuhan Air Untuk Penyiapan Lahan

Kebutuhan air untuk penyiapan lahan (land preparation)

$$IR = \frac{M e^k}{(e^k - 1)}$$

dimana :

IR = kebutuhan air irigasi ditingkat sawah untuk penyiapan lahan (mm/hr).

M = kebutuhan air untuk pengganti air yg hilang akibat evaporasi dan perkolasi.

$$M = E_0 + P$$

$$E_0 = 1,1 \times E_{To}$$

→ E_0 = evaporasi terbuka saat penyiapan lahan.

$$K = MT/S$$

→ terjangkaunya waktu penyiapan lahan.

S = air yg dibutuhkan untuk penienuhan.

Tabel A8 Nilai Koefisien Tanaman Padi

| Periode Tengah Bulanan | PADI | | | | Kedelai |
|------------------------------|-------------------|--------------------|-------------------|--------------------|---------|
| | Nedeco/Prosida | | FAO | | |
| | Varietas Biasa | Varietas Unggul | Varietas Biasa | Varietas Unggul | |
| 1 | 1,2 | 1,2 | 1,1 | 1,1 | 0,5 |

BIODATA PENULIS

Penulis dilahirkan di Surabaya Jawa Timur , 16 Juni 1993. Penulis telah menempuh pendidikan formal yaitu di SD HANG TUAH 6 Surabaya , SMP Muhammadiyah 1 Surabaya dan SMAN 3 Surabaya. Setelah lulus dari SMAN 3 Surabaya pada tahun 2011, penulis mengikuti test masuk program Diploma III Teknik Sipil yang diselenggarakan oleh ITS Surabaya dan diterima di jurusan D3 Teknik Sipil ITS Surabaya pada tahun 2011 dan terdaftar dengan NRP 3111030063. Di jurusan D3

Teknik Sipil, penulis mengambil Bidang Konsentrasi Bangunan Air. Setelah lulus dari D3 Teknik Sipil ITS, penulis mengikuti test masuk program Sarjana Lintas Jalur Teknik Sipil ITS dan diterima di Sarjana Lintas Jalur Teknik Sipil ITS pada tahun 2015 dan terdaftar dengan NRP 3115105015. Di jurusan Lintas Jalur Teknik Sipil, penulis mengambil Bidang Konsentrasi Bangunan Air.

Penulis mengucapkan terima kasih yang sebesar-besarnya kepada :

- Puja dan puji syukur kehadiran Allah SWT yang telah memberikan limpahan rahmat dan hidayahNya kepada saya untuk menyelesaikan tugas akhir ini.
- Kedua orang tua saya yang selalu mendukung dan mendoakan saya.
- Bapak Prof. Dr. Ir. Nadjadji Anwar, M.Sc selaku dosen pembimbing saya “Terima kasih banyak pak atas semua bantuannya dan bimbingannya”
- Mila Srijayanti “Terima kasih banyak teh sudah banyak membantu dalam hal apapun”
- Saudara saudara saya yang selalu mendukung saya “Terima Kasih banyak”
- Orang-orang Dinas Pekerjaan Umum (Dinas PU) Pengairan Jawa Timur dan Unit Pelaksana Teknis (UPT) Pengembangan Sumber Daya Air (PSDA) Wilayah Sungai Bengawan Solo Madiun Jawa Timur yang sudah memberikan data-data kepada kami.
- Teman – teman yg tidak bisa saya sebutkan satu per satu “Terima kasih banyak buat bantuan dan dukungannya selama ini”
